## Cs 1.6 Admin Hack V3.0 1 \_\_LINK\_\_

The Logincontacts WordPress plugin is vulnerable to Stored Cross-Site Scripting due to insufficient input validation in the `/inc/functions.php` script where a user with administrative privileges is able to inject arbitrary web scripts, in versions up to and including 1.4.1. This only affects multi-site installations where `unfiltered_html` is disabled for administrators, and sites where `unfiltered_html` is disabled. The Ultimate Settings WordPress plugin is vulnerable to Remote Code Execution due to an oversight in the options-page functionality found in the `/plugins/UltimateSettings/functions.php` script where an attacker with administrative privileges is able to upload arbitrary files, in versions up to and including 3.6. In contrast to the `file_ext_filter` filter which is supposed to prevent the uploading of PHP files by users without permissions, this filter isn't. By uploading a PHP file, an attacker is able to trick the users into opening it as an HTML file and thus make malicious actions possible. The Haja & Halkları WordPress plugin is vulnerable to Stored Cross-Site Scripting due to insufficient input validation in the `/inc/admin/components/haja.php` script where a user with administrative privileges is able to inject arbitrary web scripts, in versions up to and including 1.0.2. This only affects multi-site installations where `unfiltered_html` is disabled for administrators, and sites where `unfiltered_html` is disabled. The WPPerf plugin is vulnerable to Remote Code Execution via an internal email. In version 1.3, an attacker is able to specify the email address of a user with administrative privileges to include the following code, which would let an attacker to execute arbitrary PHP code on the system via `mail()` function.

## Cs 1.6 Admin Hack V3.0 1

Finally, for the 'X+Y' test, the hacker goes through the first fingerprint A, applies the R function, and calculates two passwords, X and Y. Then goes through the second fingerprint B, applies R to it, and calculates two more passwords, X and Y. This calculation is repeated until the hacker finds a fingerprint where 'X' and 'Y' are in the same digit position. For example, the hacker finds two fingerprints, F and J, with a '1' on the first and second. That means one password must be '1' and another must be '1'. Then the hacker would look up the fingerprint J in the table (Fingerprint F in the example below) and identify its corresponding password (Password F). The Password Genius plugin is vulnerable to Stored Cross-Site Scripting due to insufficient input validation and sanitization via several parameters found in the class/Plugin.php file which allowed attackers with administrative user access to inject arbitrary web scripts, in versions up to and including 2.0. This affects multi-site installations whereunfiltered\_htmlis disabled for administrators, and sites whereunfiltered\_htmlis disabled. To summarize, by knowing the beginning and end of each chain of computations (the only things that are stored during precomputation), a hacker can retrieve any password from a fingerprint. In somewhat simplistic terms, starting from a stolen fingerprint that hacker would apply the R andhfunctions repeatedly, calculating a series of passwords and fingerprints until reaching a fingerprint with 20 zeros in front of it. The hacker would then look up that final fingerprint in the table (Fingerprint C in the example below) and identify its corresponding password (Password C). 5ec8ef588b
